Characterization of glycans of CD4+T cells in HAM/TSP

Daisuke Kodama^{1*}, Kimiko Izumo¹, Ryuji Kubota¹, Toshio Matsuzaki², Hiroshi Takashima³, Shuji Izumo¹*From* 16th International Conference on Human Retroviruses: HTLV and Related Viruses
Montreal, Canada. 26-30 June 2013

The outermost structure of cells is galectin-glycan lattice, that is shown to have many roles in cell-cell interactions. Recently, biofilm-like extracellular viral assemblies were shown to mediate HTLV-1 cell-to-cell transmission. Here, we tried to characterize the glycans on the CD4+T cells in HAM. CD4+T cells from four respective cases of HAM, AC(asymptomatic carriers), and NC(negative control) were subjected to lectin array analysis. Similarly, glycans liberated from membrane proteins of CD4+T cells from six respective cases of HAM and NC analyzed by MALDI-TOF MS. We found that UDA(*Urtica dioica* agglutinin) and STL(*Solanum tuberosum* lectin (Potato)) lectins, that recognize N-glycan polylactosamine which consist of repeats of the disaccharide betaGal(1-4) betaGlcNAc(1-3), were significantly high in HAM in lectin array analysis. Interestingly, UDA was reported to inhibit cell-to-cell infection in vitro. On the other hand, MALDI-TOF MS analysis found several O-glycans in HAM. Candidates verified in GlycoSuite database were mainly O-glycans attach to MUC1 and Leukosialin (CD43) as carrier proteins. These proteins were reported to play roles in ATL and cell-to-cell infection as well. These glycans and carrier proteins may be therapeutic target of HAM.
